Abstract

This project delivers a real-time monitoring and alerting framework for ADF pipelines that reduces time-to-detection and operational risk. It integrates ADF platform metrics with Azure Monitor’s time-series store, configures rule-based alerts (1-minute evaluation, 5-minute lookback), and routes notifications through action groups (email, SMS). A KPI-driven dashboard consolidates pipeline and activity level metrics to provide central operational visibility and support rapid incident response.

Why this matters

Business Impact

Pipeline failures cause downstream data delays, SLA breaches, and potential revenue loss. Faster detection reduces cost and preserves trust in analytics.

Operational Efficiency

Automated alerts and centralized KPIs reduce manual checks and mean-time-to-repair (MTTR) for data engineering teams.

Scalability

Metric-driven rules and action groups scale across environments and multiple factories without manual configuration per pipeline.

Existing Solutions & Problems

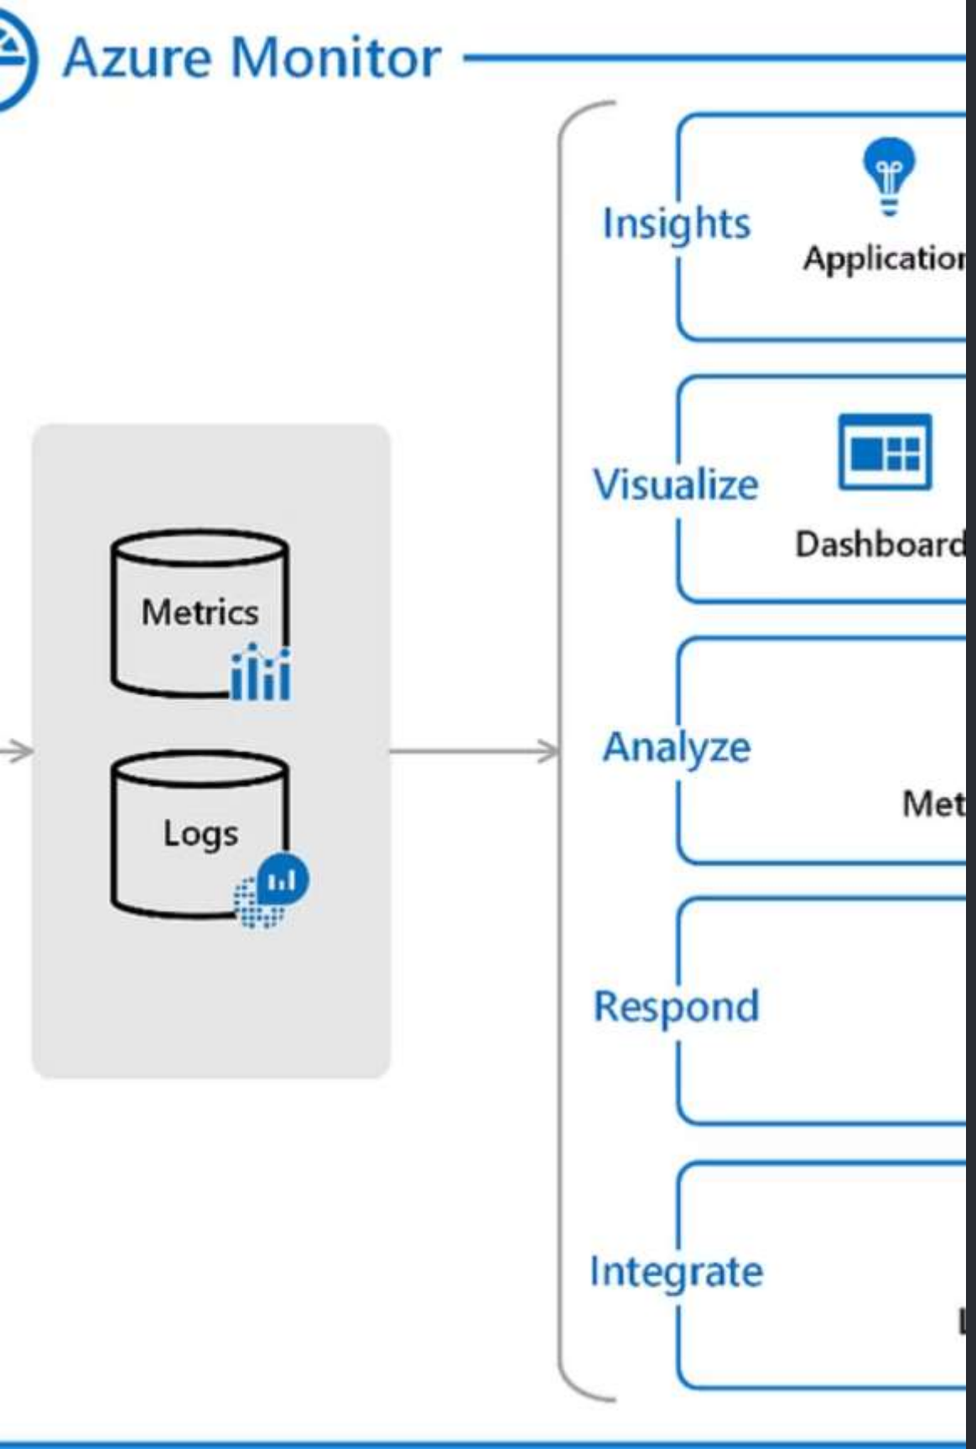
Common Approaches

Manual checks in the ADF Monitor tab, post-failure log review, ad hoc notifications (email/webhooks) with limited thresholding.

Key Problems

Delayed detection, missing threshold-based rules, lack of centralized KPI view, and reliance on human supervision increase operational risk.

These limitations produce inconsistent responses and longer outages. A deterministic, metric-driven approach is required for consistent, auditable monitoring.



Proposed Solution — Overview

A real-time monitoring framework that: (1) captures ADF pipeline and activity metrics, (2) stores metrics in Azure Monitor, (3) evaluates alert rules every minute using a 5-minute lookback, (4) triggers action groups for email/SMS, and (5) feeds a KPI dashboard for operational visibility.

System Architecture

This architecture ensures continuous metric ingestion and rapid alerting. Each component is decoupled to allow independent scaling and clear observability.

Project Workflow — Step-by-step

01

1. Execute Pipeline

ADF pipeline runs produce runtime metrics (success/failure counts, activity durations, error codes).

02

2. Ingest Metrics

Metrics are emitted to Azure Monitor (platform metrics) and retained for short-term time-series analysis.

03

3. Rule Evaluation

Alert rule evaluates metric (Count > 0) with 1-minute frequency and 5-minute lookback to detect failures quickly while reducing noise.

04

4. Notification & Dashboard

On alert, action group sends email/SMS and dashboard widgets update to reflect current failure state and trends.

Dashboard & KPIs

1.

Operational Panels

Failed Pipeline Runs (Last 1 hour), Failed Activity Runs, Successful Pipeline Runs, and Failure Trend (24 hours).

2.

Alert Triage

Clickable drill-throughs to pipeline run logs, related activity errors, and recommended remediation steps for engineers and SREs.

3.

Business KPIs

SLAs met, MTTR, failure frequency per pipeline, and trend anomalies to support stakeholder reporting.

Expected Output & Measurable Impact

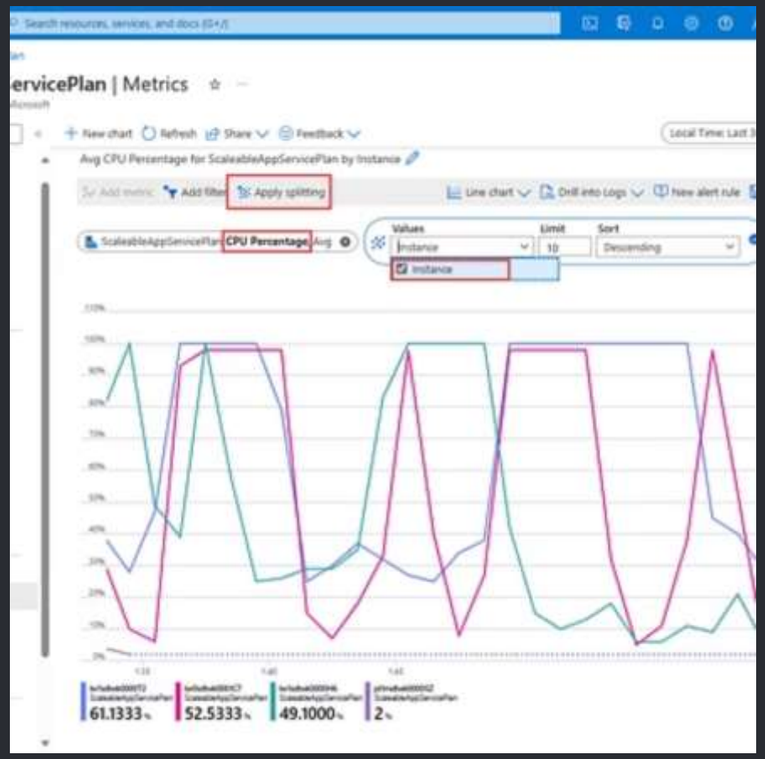
Deliverables

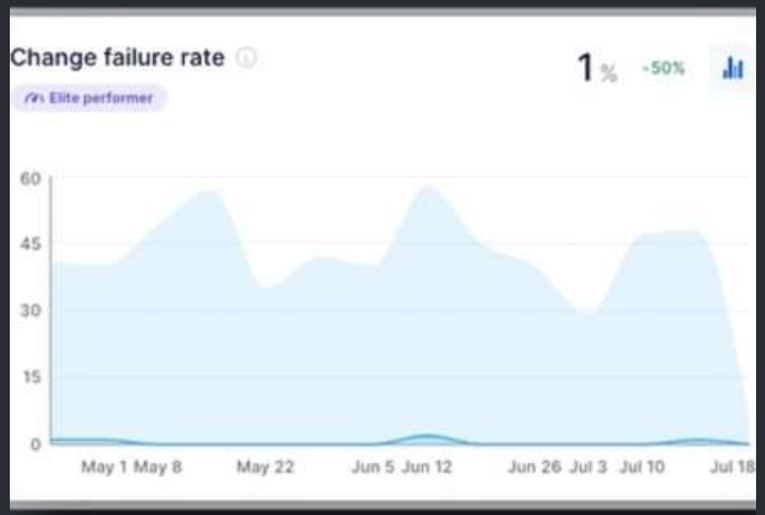
Real-time alerts (1–2 minutes), automated email/SMS via action groups, centralized KPI dashboard, and documented runbooks for incident response.

Impact Metrics

Reduced manual monitoring hours, faster detection and resolution (target MTTR reduction of 40–60%), improved SLA compliance and operational confidence.

Next Steps, Validation & References





Next steps: implement in a staging subscription, validate rules against simulated failures, tune thresholds and noise suppression, formalize runbooks, then rollout to production.
